This week you will get practice applying the exponential and logistic models and describing their qualitative behaviour. Some of these questions take a bit of thought, they are good practice if you generally struggle with word problems. You will also get a lot of practice solving separable differential equations.

*Numbers in parentheses indicate the question has been taken from the textbook:

S. J. Schreiber, Calculus for the Life Sciences, Wiley,

and refer to the section and question number in the textbook.

- 1. (6.1) Write a differential equation to model the situations described below. Do not try to solve.
 - (a) (6.1-1) The number of bacteria in a culture grows at a rate that is proportional to the number of bacteria present.
 - (b) (6.1-2) A sample of radium decays at a rate that is proportional to the amount of radium present in the sample.
 - (c) (6.1-5) According to Benjamin Gompertz (1779-1865) the growth rate of a population is proportional to the number of individuals present, where the factor of proportionality is an exponentially decreasing function of time.
 - (d) (6.1-7) The rate at which an epidemic spreads through a community of P susceptible people is proportional to the product of the number of people y who have caught the disease and the number P-y who have not.
 - (e) (6.1-8) The rate at which people are implicated in a government scandal is proportional to the product of the number N of people already implicated and the number of people involved who have not yet been implicated.
- 2. (6.1) A population model is given by

$$\frac{\mathrm{d}P}{\mathrm{d}t} = P(100 - P).$$

- (a) (6.1-9) For what values is the population at equilibrium?
- (b) (6.1-10) For what values is $\frac{dP}{dt} > 0$?
- (c) (6.1-11) For what values is $\frac{dP}{dt} < 0$?
- (d) (6.1-12) Describe how the fate of the population depends on the initial density.
- 3. (6.1) A population model is given by

$$\frac{\mathrm{d}P}{\mathrm{d}t} = P(P-1)(100-P).$$

- (a) (6.1-13) For what values is the population at equilibrium?
- (b) (6.1-14) For what values is $\frac{\mathrm{d}P}{\mathrm{d}t} > 0$?
- (c) (6.1-15) For what values is $\frac{dP}{dt} < 0$?
- (d) (6.1-16) Describe how the fate of the population depends on the initial density.
- 4. (6.1) Radioactive decay: Certain types of atoms (e.g. carbon-14, xenon-133, lead-210, etc.) are inherently unstable. They exhibit random transitions to a different atom while emitting radiation in the process. Based on experimental evidence, Rutherford found in the early 20th century that the number, N, of atoms in a radioactive substance can be described by the equation

$$\frac{\mathrm{d}N}{\mathrm{d}t} = -\lambda N$$

where t is measured in years and $\lambda > 0$ is known as the *decay constant*. The decay constant is found experimentally by measuring the half life, τ of the radioactive substance (i.e. the time it takes for half of the substance to decay). Use this information in the following problems.

- (a) (6.1-18) Find a solution to the decay equation assuming that $N(0) = N_0$.
- (b) (6.1-19) For xenon-133, the half-life is 5 days. Find λ . Assume t is measured in days.
- (c) (6.1-20) For carbon-14 the half life is 5, 568 years. Find the decay constant λ , assuming t is measured in years.
- (d) (6.1-21) How old is a piece of human bone which contains just 60% of the amount of carbon-14 expected in a sample of bone from a living person, assuming the half life of carbon-14 is 5,568 years?
- (e) (6.1-22) The Dead Sea Scrolls were written on parchment at about 100 B.C. What percentage of carbon-14 originally contained in the parchment remained when the scrolls were discovered in 1947?
- 5. (6.1-30) Hyperthyroidism is caused by a new growth of tumor-like cells that secrete thyroid hormones in excess to the normal hormones. If left untreated, a hyperthyroid individual can exhibit extreme weight loss, anorexia, muscle weakness, heart disease intolerance to stress, and eventually death. The most successful and least invasive treatment option is radioactive iodine-131 therapy.

This involves the injection of a small amount of radioactivity into the body. For the type of hyperthyroidism called Graves disease, it is usual for about 40 - 80% of the administered activity to concentrate in the thyroid gland. For functioning adenomas (hot nodules), the uptake is closer to 20 - 30%. Excess iodine-131 is excreted rapidly by the kidneys. The quantity of radioiodine used to treat hyperthyroidism is not enough to injure any tissue except the thyroid tissue, which slowly shrinks over a matter of weeks to months. Radioactive iodine is either swallowed in a capsule or sipped in solution through a straw. A typical dose is 5 - 15 millicures. The half-life of iodine-131 is 8 days.

- (a) Suppose that it takes 48 hours for a shipment of iodine-131 to reach a hospital. How much of the initial amount shipped is left once it arrives at the hospital?
- (b) Suppose a patient is given a dosage of 10 millicures of which 30% concentrates in the thyroid gland. How much is left one week later?
- (c) Suppose a patient is given a dosage of 10 millicures of which 30% concentrates in the thyroid gland. How much is left 30 days later?
- 6. (6.2) Solve the following differential equations.
 - (a) $\frac{dy}{dt} = 5y$
 - (b) $\frac{\mathrm{d}y}{\mathrm{d}t} = -y$
 - (c) $\frac{\mathrm{d}y}{\mathrm{d}x} = -3y$
 - (d) $\frac{dy}{dx} = 0.2y$
 - (e) $(6.2-17) \frac{dy}{dt} = y^3$
 - (f) $(6.2-18) \frac{dy}{dt} = y \sin t$
 - (g) $(6.2-20) \frac{dy}{dt} = \frac{t}{y}$
 - (h) $(6.2-24) \frac{dy}{dx} = \frac{x}{y}\sqrt{1+x^2}$
 - (i) (6.2-26) $\frac{\mathrm{d}y}{\mathrm{d}x} = \frac{\sin x}{\cos y}$
 - (j) (6.2-30) $\frac{dy}{dt} = yt$ with y(1) = -1
 - (k) (6.2-32) $\frac{\mathrm{d}y}{\mathrm{d}t} = e^{-y}t$ with y(-2) = 0
 - (l) (6.2-34) $\frac{dy}{dt} = ty^2 + 3t^2y^2$ with y(-1) = 2
 - (m) $\frac{dy}{dx} = y \sin x + \frac{y}{(x+1)^2}$ with y(0) = 1
 - (n) $\frac{dy}{dx} = \frac{x}{y}e^{-x^2}$ with y(0) = 1
 - (o) $\frac{dy}{dx} = y + ye^x$ with y(0) = e

7. (6.2-44) Populations may exhibit seasonal growth in response to seasonal fluctuations in resource availability. A simple model accounting for seasonal fluctuations in the abundance N of a population is

$$\frac{\mathrm{d}N}{\mathrm{d}t} = (R + \cos t)N$$

where R is the average per-capita growth rate and t is measured in years.

- (a) Assume R = 0 and find a solution to this differential that satisfies $N(0) = N_0$. What can you say about N(t) at $t \to \infty$?
- (b) Assume R = 1 (more generally R > 0) and find a solution to this differential that satisfies $N(0) = N_0$. What can you say about N(t) at $t \to \infty$?
- (c) Assume R=1 (more generally R<0) and find a solution to this differential that satisfies $N(0)=N_0$. What can you say about N(t) at $t\to\infty$?
