- PS8, question 3, 4

Often it is impossible to solve a differential equation. E.g.

$$\frac{\mathrm{d}y}{\mathrm{d}t} = y^2 + t$$

(the *Riccati equation*) has no solutions that can be written in terms of usual functions like $\sin x$, e^x , etc.

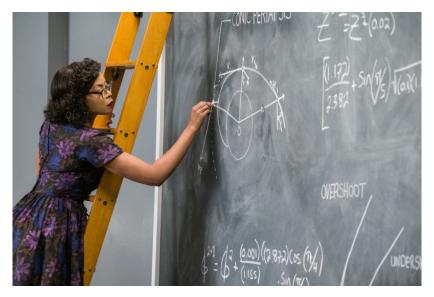

Often it is impossible to solve a differential equation. E.g.

$$\frac{\mathrm{d}y}{\mathrm{d}t} = y^2 + t$$

(the *Riccati equation*) has no solutions that can be written in terms of usual functions like $\sin x$, e^x , etc.

We want a method to estimate y(t) is we know that $y(t_0) = y_0$.

Let's use Eulers method!

Suppose y(t) is a solution to

$$\frac{\mathrm{d}y}{\mathrm{d}t}=f(t,y)$$

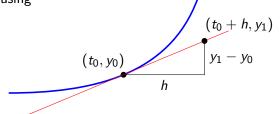

and that $y(t_0) = y_0$.

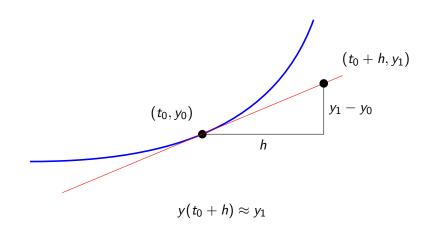

Suppose y(t) is a solution to

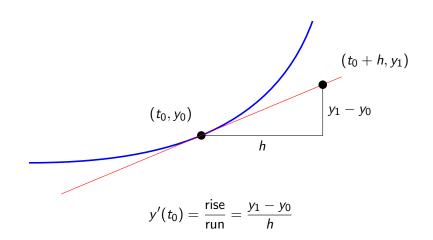

$$\frac{\mathrm{d}y}{\mathrm{d}t}=f(t,y)$$

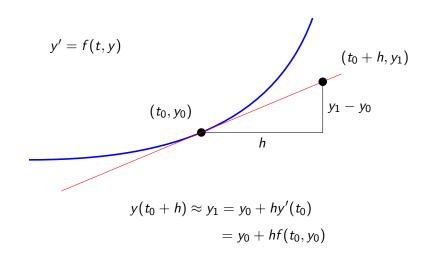

and that $y(t_0) = y_0$.

If h is a small number (e.g. h = 0.1), then we approximate $y(t_0 + h)$ using

$$\frac{\mathrm{d}y}{\mathrm{d}t}=f(t,y)$$

If we know that the solution satisfies $y(t_0) = y_0$ then

• let h be a small step forward in time

$$\frac{\mathrm{d}y}{\mathrm{d}t} = f(t,y)$$

If we know that the solution satisfies $y(t_0) = y_0$ then

- let h be a small step forward in time
- we can get an approximate value for the solution at
 t = t₀ + h = t₁

$$\frac{\mathrm{d}y}{\mathrm{d}t} = f(t,y)$$

If we know that the solution satisfies $y(t_0) = y_0$ then

- let h be a small step forward in time
- we can get an approximate value for the solution at $t = t_0 + h = t_1$
- i.e. $y(t_1) \approx y_1$ where

$$y_1 = y_0 + hf(t_0, y_0)$$

To carry out Eulers method, we simply repeat this a number of times!

$$\frac{\mathrm{d}y}{\mathrm{d}t} = f(t,y)$$

Given an initial value $y(t_0) = y_0$. To approximate y(t) at t = a follow the steps:

Choose an increment h

To carry out Eulers method, we simply repeat this a number of times!

$$\frac{\mathrm{d}y}{\mathrm{d}t}=f(t,y)$$

- Choose an increment h
- set $t_1 = t_0 + h$

To carry out Eulers method, we simply repeat this a number of times!

$$\frac{\mathrm{d}y}{\mathrm{d}t}=f(t,y)$$

- Choose an increment h
- set $t_1 = t_0 + h$
- set $y_1 = y_0 + hf(t_0, y_0)$

To carry out Eulers method, we simply repeat this a number of times!

$$\frac{\mathrm{d}y}{\mathrm{d}t}=f(t,y)$$

- Choose an increment h
- set $t_1 = t_0 + h$
- set $y_1 = y_0 + hf(t_0, y_0)$
- set $t_2 = t_1 + h$

To carry out Eulers method, we simply repeat this a number of times!

$$\frac{\mathrm{d}y}{\mathrm{d}t}=f(t,y)$$

- Choose an increment h
- set $t_1 = t_0 + h$
- set $y_1 = y_0 + hf(t_0, y_0)$
- set $t_2 = t_1 + h$
- set $y_2 = y_1 + hf(t_1, y_1)$

To carry out Eulers method, we simply repeat this a number of times!

$$\frac{\mathrm{d}y}{\mathrm{d}t}=f(t,y)$$

- Choose an increment h
- set $t_1 = t_0 + h$
- set $y_1 = y_0 + hf(t_0, y_0)$
- set $t_2 = t_1 + h$
- set $y_2 = y_1 + hf(t_1, y_1)$
- keep repeating until $t_n \approx a$

To carry out Eulers method, we simply repeat this a number of times!

$$\frac{\mathrm{d}y}{\mathrm{d}t}=f(t,y)$$

- Choose an increment h
- set $t_1 = t_0 + h$
- set $y_1 = y_0 + hf(t_0, y_0)$
- set $t_2 = t_1 + h$
- set $y_2 = y_1 + hf(t_1, y_1)$
- keep repeating until $t_n \approx a$
- then $y(a) \approx y_n$.

We will aprroximate y(2), where y obeys

$$\frac{\mathrm{d}y}{\mathrm{d}t} = y^2 + t$$
